

PRIMUS

LCSA and beyond: a demonstrator case study using LCSA, plastic littering, circularity and system dynamics for the **PRIMUS** project

Results

System Dynamics

System Dynamics main conclusions I

- A growing demand/production of plastics, and not enough recycling rates make a “circular economy” hard to reach.
- Recycled plastic market supply is a concern.
- Due to an increase in production expected over the years, environmental impacts become worse per year.
- However, LCA impact categories do show an improvement for the recycled product scenarios.

System Dynamics main conclusions II

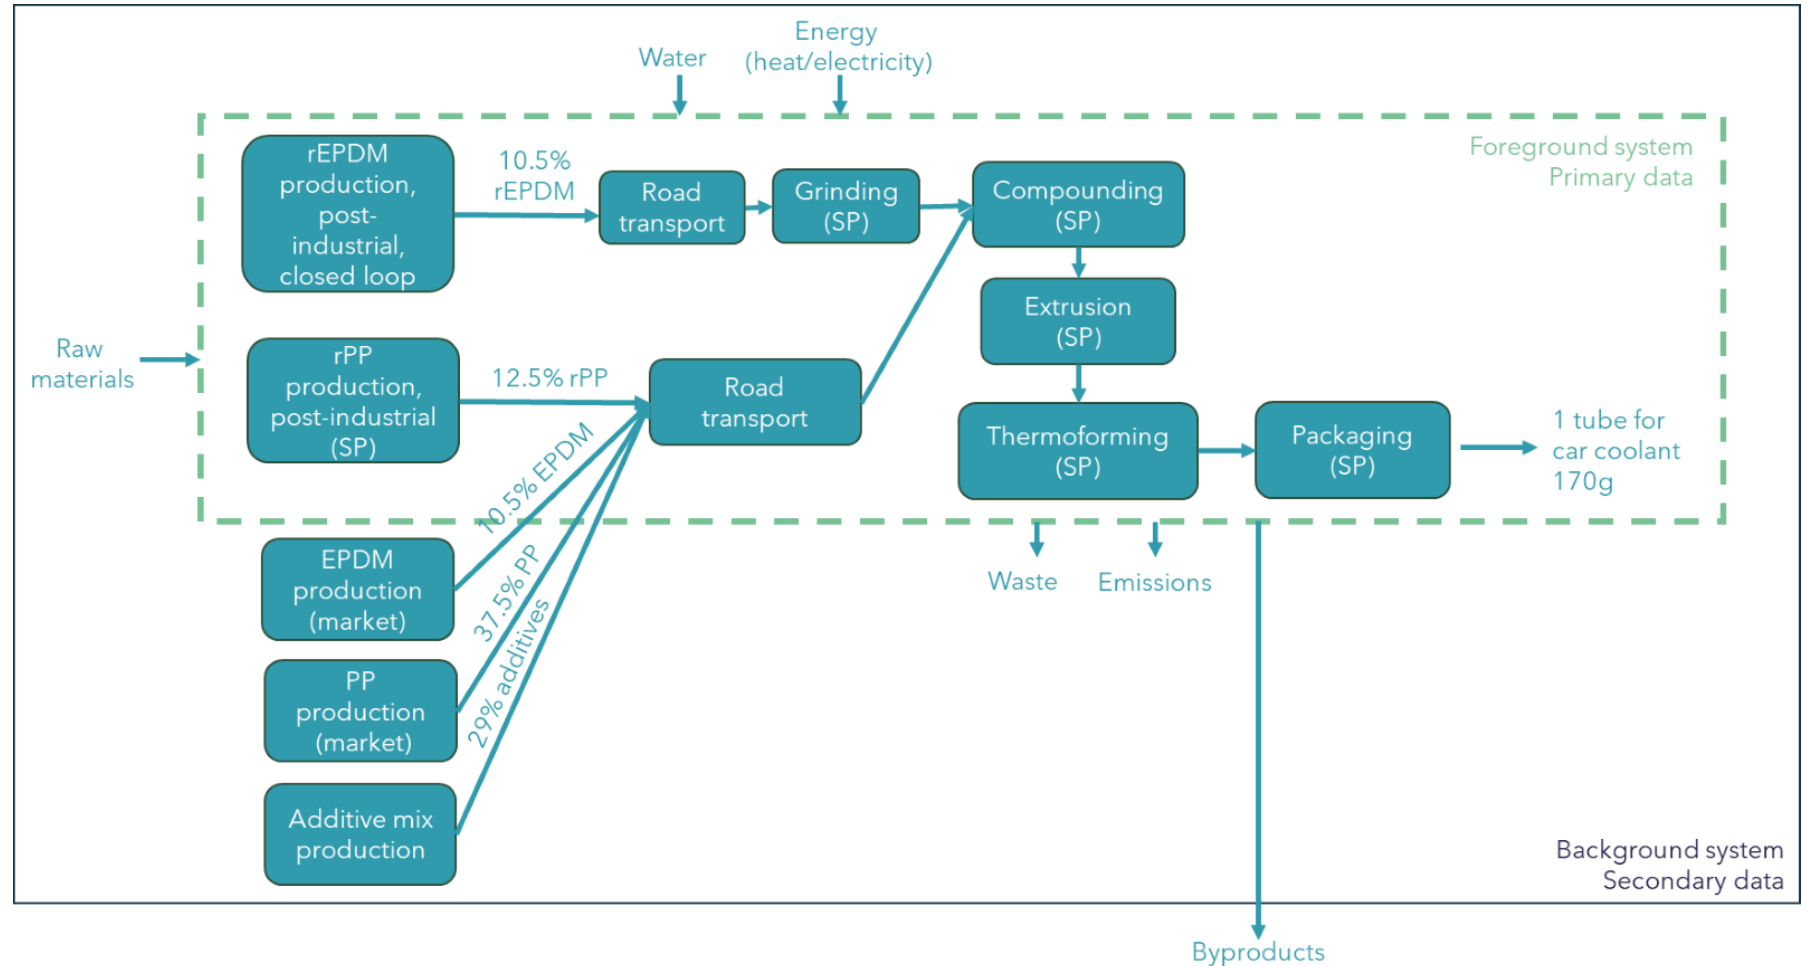

- Littering is the most common EoL fate and is often overseen in assessments. It doesn't show a decrease in the recycling scenarios.
- The most effective way to reduce overall littering of plastics is EoL alternatives to landfill.
- Unwanted substances in plastic products will be prolonged in the use phase if we recycle products.

Results

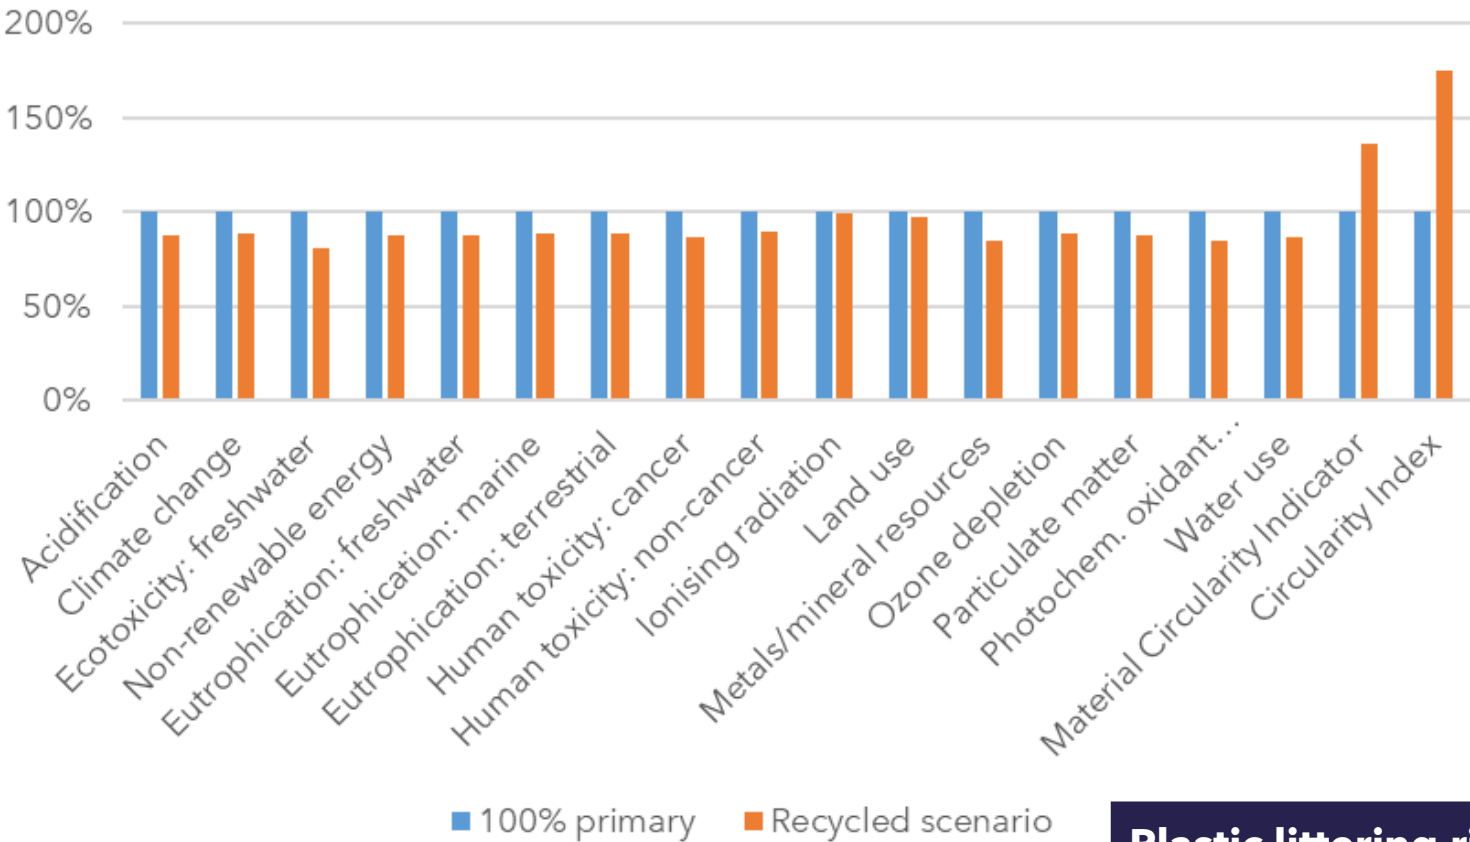

Demonstrator Cases

DEMO 2 results

DEMO 2 results – tube car coolant

DEMO 2 relative LCA and circularity results

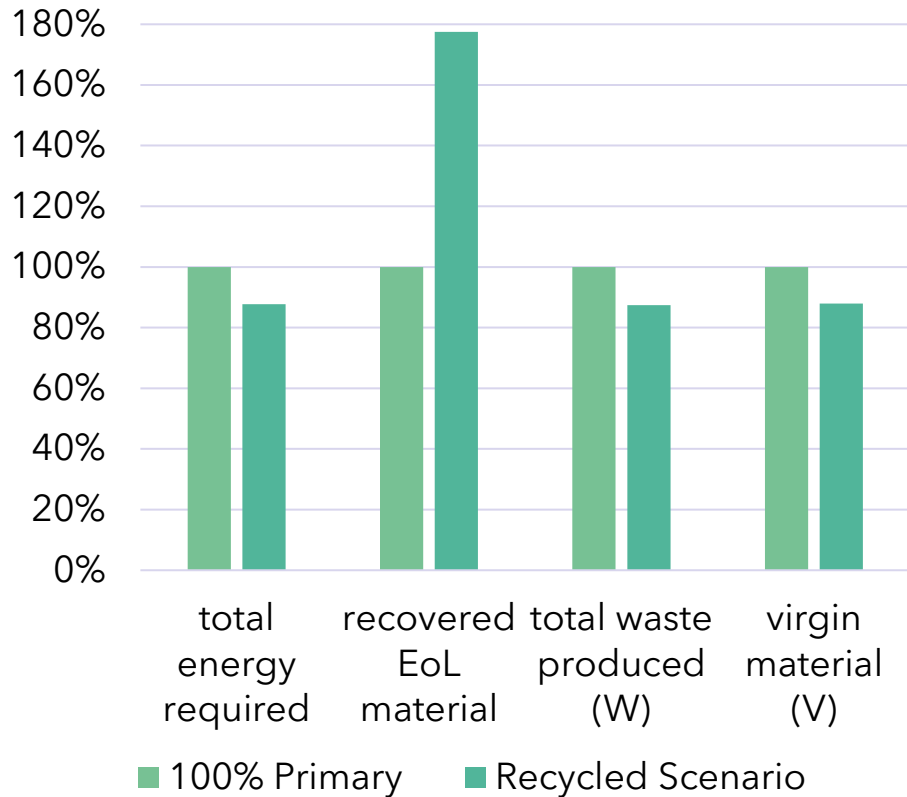

Hotspots

- Plastic material
- Carboard box (packaging)
- Natural gas (thermoforming)

Plastic littering risk	0.00917	0.00906	kg
------------------------	---------	---------	----

DEMO 2 results – tube car coolant

More on Circularity

Around 13% less

- Total energy required
- Total primary material required

A 10% decrease in performance would give a worse MCI circularity score compared to the 100% primary counterpart.

Conclusions

Conclusions I

- A **full sustainability framework** was developed as part of the PRIMUS Sustainability Methodology involving Life Cycle Assessment (LCA), Social LCA, Circularity, plastic littering risk and System Dynamics.
- The methodology was applied to the **4 PRIMUS demonstrator cases**.
- Sustainability assessments show **general improvements** when using recycling content, where impacts like Climate Change always show a decrease in emissions.

Conclusions II

- Only **Demo 3** shows a mix between improvements and worse results, mainly due to the large transportation distance of recycled content and intensive energy and nitrogen use in the specific demo recycling process.
- Furthermore, a higher plastic littering risk is generally seen in the recycled plastic scenarios.
- However, results would change if a full cradle-to-grave rather than cradle-to-gate analysis was considered, as e.g. landfilling plastic products is considered to have higher plastic littering risk than recycling them.
